

PART 1 · Git Branching & Pull Requests

Step 1 - Repository Setup

- One partner creates a new GitHub repo named: se250-lab2-[lastnames]
- Go to Settings → Collaborators and invite your partner
- Both partners clone the repo to your local machine: `git clone [repo url]`

Step 2 - Create Feature Branches

- Partner A: `git checkout -b feature/partner-a`
- Partner B: `git checkout -b feature/partner-b`
- Both: verify your branch with `git branch` (you should see your branch highlighted)

Step 3 - Make Changes & Commit

- Partner A: create a file called partner-a.txt and write 3 sentences about why you chose this major
- Partner B: create a file called partner-b.txt and write 3 sentences about a software product you use every day
- Both: `git add .` → `git commit -m "Add [your name]'s file"` → `git push origin [your branch]`

Step 4 - Open Pull Requests

- Both partners go to GitHub → open a Pull Request from your branch to main
- Title: "Add [your name]'s file"
- In the description, write one sentence summarizing what you changed

Step 5 - Review & Merge

- Click on your partner's pull request and go to the Files Changed tab
- Leave at least one comment (a question, observation, or suggestion)
- Approve the PR and merge it - repeat for the second PR
- Both partners run: `git checkout main` → `git pull origin main`
- Verify both files are now in your local main branch

Step 6 - Screenshot & Reflect

- Screenshot your GitHub repository showing both merged pull requests in the Pull Requests tab
- Write 2–3 sentences: what was the hardest part of this workflow, and why do teams use it?
